Introduction

Cloud computing has become an important technology to consider for organizations that are looking to optimize their IT operations and reduce operating costs. Until now, leveraging the cloud involved either setting up and running applications in the cloud and managing them long-term off-premise, or running services as a one-time event. Migrating existing services, applications, and virtual machines to the cloud presented immense networking complexities, and if performed outside a local data center, was a non-trivial challenge. Moving live services without user interruption was virtually impossible.

F5 and VMware have developed a joint solution to this overcome these limitations and enable enterprise customers to migrate application services between clouds without user impact.

Live virtual machine (VM) migration—moving a VM from one physical server to another while the machine is running and processing transactions—has been one of the core technologies propelling virtualization’s mass adoption in the data center. Live migration enables a more dynamic and agile environment as virtual systems flow between hardware devices based on usage, consumption, availability, and so on. VMware has been both a technological innovator and market leader in live system migration. Until recently, however, even this advanced technology was generally relegated to use within a local data center, staying confined to one physical network.

The F5 and VMware cloud migration solution moves VMotion™ from the binds of the local data center and enables live migration of both VMs and the back-end storage across the WAN between data centers and clouds. F5 has created a workflow that automates the majority of the migration, making it possible to execute these migrations with a minimum of manual configuration.

VMware VMotion Basics

VMware’s VMotion is a unique technology that moves running virtual machines from one physical server to another without interrupting the VM or the applications running on that VM. During a VMotion event, active memory and CPU running state (which combined include the current state of the network and any applications running on the VM) are transferred between physical systems as needed based on resource constraint, disaster recovery, or functional changes (such as bringing down

a physical server). The storage back-end associated with that virtual machine—the VMDK and configuration files located on the storage network—can also be migrated between storage networks with VMware Storage VMotion.

Design Factors: VMotion Between Networks

One of the primary design considerations for VMotion is network topology. During a VMotion migration, a snapshot of the running systems is transferred from one server to another. Since the running state of a system is a “moment in time” snapshot, there is no way to change anything in the running state, including the IP address of the virtual machine or any other network settings.

For the VM to resume operations and keep running on the new server, the destination network must be exactly the same as the original network housing the VM, as must the network configuration of the VM itself. The virtual machine and physical server network configurations include the IP address of the VM, the IP network settings such as subnet mask and gateway address, and VLAN configurations on the VMware ESX™ server. The VM must stay within the same broadcast domain in order for the virtual network to resume without application data loss.

Design Factors: VMotion Over Distance

Beyond local network topology issues, one of the common questions when deploying VMware as part of a cloud or high availability/disaster recovery (HA/DR) scenario has been “Can I move virtual machines between data centers?” Some of the challenges with long distance VMotion are the WAN bandwidth, latency, and packet loss limitations that are outside the control of most IT organizations. Many applications, including VMotion live migration, are susceptible to network issues across the WAN that can be exacerbated by distance and network quality. Although not as time-sensitive as VM live migration, Storage VMotion can also suffer from latency issues over the WAN. If the conditions are bad enough, attempted VMotion events will simply fail.

Other challenges with external data center VMotion events include managing user connections and application data during the migration, and IP management and reclamation. In a LAN migration, user connections are moved from one physical switch port to another. The VM and active user connections never leave their configured network nor is there a need to manage or change the VM IP address because that IP address stays within the local network. With a long distance or

62% of IT organizations reported that the ability to move virtual machines between data centers (e.g. long distance VMotion) is valuable when choosing a cloud provider.

cloud VMotion move, however, the VM must traverse multiple networks without losing any user or application state information. The user connections are routed to a geographically removed location and IP addresses need to be managed between the two data centers.

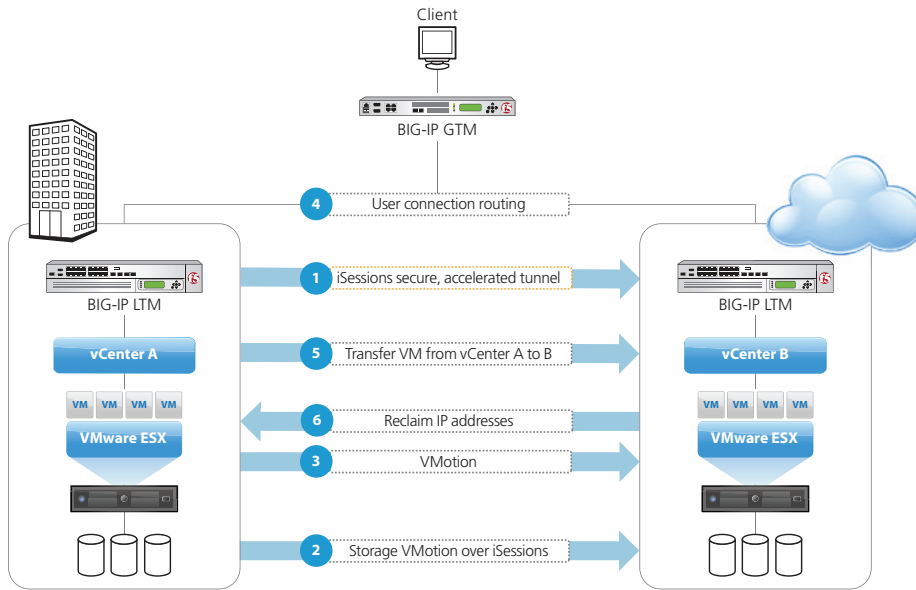

Each of these long distance challenges—WAN constraints and user connection management—become more of an issue with “sticky apps”: applications that have a very intensive user experience, such as web 2.0 applications.

Connecting Clouds with BIG-IP Solutions

F5 has been an Application Delivery Networking pioneer in managing traffic across distributed data centers and the cloud, as well as in optimizing application traffic in and out of the data center. By working with VMware to address the difficulties inherent in migrating an application to the cloud automatically and seamlessly, F5 has created a solution that optimizes, secures, and manages VM migration and user connections between data centers, effectively “connecting clouds.” Beyond network optimizations and security, transitioning user connections from one cloud to another is the key element in moving VMs between data centers. User experience is paramount, and it’s critical that the application does not suffer any significant downtime or loss of application data during or after a cross-site live migration.

Building a Successful Data Center-to-Cloud Network

When designing a solution for VMotion over distance, F5’s goal was to create a system that enables secure live migrations between multiple cloud-based data centers without any interruption in the application service or user downtime. F5 has accomplished this goal using a suite of existing F5 products and technologies that already plug into vCenter™ for VM application networking management: BIG-IP® Local Traffic Manager™ (LTM), BIG-IP® Global Traffic Manager™ (GTM), BIG-IP® integrated WAN optimization services, iSessions™ tunneling between data centers, and iControl®, the open API used to manage the migration through vCenter.

Cloud-based live VM migration with F5 and VMotion

Step-by-Step Solution Walkthrough

1. iSessions Tunnel

The first step in building an infrastructure to support secure live migration between clouds and data centers is to symmetrically connect each data center using a feature of F5 BIG-IP LTM: iSessions tunnels. Using SSL and advanced data compression techniques, BIG-IP LTM creates secure and optimized tunnels between each data center to carry the VMotion traffic. This enables applications within each data center to communicate efficiently over the private connection and creates the infrastructure to support the storage and VM migrations.

2. Storage VMotion

Once the iSessions infrastructure is in place, initiating a Storage VMotion event is the first step in actually moving the VM from one data center to the other. Different trigger mechanisms are possible (e.g. VMware vCenter Orchestrator™); however, ultimately vCenter will trigger a Storage VMotion event and begin migrating the virtual disks between the primary and secondary data centers. All application traffic will continue to flow to the VM located in the primary data center and vCenter in that data center will still retain control over the VMs tied to the Storage VMotion event. The storage data is passed through the secure and optimized iSessions tunnel over the WAN connection.

3. VM VMotion

Once the Storage VMotion event finishes, vCenter in the primary data center will trigger a standard VMotion event to move the running VM to the secondary data center. VMotion will be moving the VM over the iSessions tunnel to an ESX server located in the secondary data center which, due to the iSessions tunnel, is part of the same network as the primary data center. During the migration event, vCenter at the primary data center will remain in control of the transplanted VM.

4. Data Center Connection Redirection

After successful completion of the VMotion migration event to the secondary data center, BIG-IP LTM at the secondary data center will recognize that the application is up and available. BIG-IP LTM at the primary data center will start routing existing connections through the iSessions tunnel to the VM now running at the secondary data center. BIG-IP GTM will also begin sending any new connections directly to the migrated VM in the secondary data center. As the existing user connections naturally terminate, all application traffic will be routed natively to the secondary data center.

5. vCenter VM Re-registration

After the migrated VM is up and running in the secondary data center and all application traffic is being routed to that machine, BIG-IP LTM will send an instruction to the vCenter consoles at both data centers, turning over VM management to vCenter in the secondary data center. vCenter in the primary data center will stop managing the migrated VM, thus completing the long-distance VMotion event. The entire VM bundle, from storage up through management, is now live and serving users out of the secondary data center, and the VM in the primary data center can be shut down.

6. IP Reclamation

In the event of a one-way move where the VMotion migration is a more permanent relocation, the original IP space for the VM in the primary data center can be reclaimed and reused for other applications. Once the migration is complete—vCenter in the secondary data center has assumed control of the VM and all user connections are being routed to the secondary data center—the IP addresses in the primary data center (both local/internal and external) can be reclaimed and reused for other applications.

Tech Brief

Connecting to the Cloud with F5 BIG-IP Solutions and VMware VMotion

Conclusion

VMware has changed the way we build data centers, and cloud computing is changing how we think about local and remote data centers. Moving applications and running servers between hardware platforms enables us to create a very fluid and agile IT infrastructure to support new business needs. Yet these solutions are not seamless out of the box and often don't factor in the application needs and user experience.

Not only does F5 enable long distance VMotion events from cloud to cloud, but the same solution can be deployed within the local data center to migrate running VMs from one physical network to another physical network (assuming the VM network configuration remains unaltered). This solution can help move VMs from the dev/staging network into production, or move a running VM between security zones such as the DMZ and the private network.

Regardless of whether you're using F5 BIG-IP solutions to manage VMotion events within the data center, between private clouds, or between private and public clouds, the application delivery technology remains the same. iSessions keeps the data secure in transit and optimizes the WAN for accelerated and reliable delivery of the storage and VM data. The VMware API enables BIG-IP solutions to request re-registration of the migrated VMs within vCenter in the destination cloud or data center. BIG-IP LTM and BIG-IP GTM manage user connections to the application to ensure that no user data is lost and that the applications remain online and available.

This integrated solution between F5 and VMware enables long distance VMotion for the first time between data centers and clouds. The solution works with your existing network and IT infrastructure; it does not require a re-architecture of your local or remote networks. This seamless solution uses existing technologies from both F5 and VMware to enable transparent live VM migration over long distances, guaranteeing the applications are migrated in a secure and optimized manner and always remain available before, during, and after the VMotion migration. Moving your applications and services transparently between clouds is now possible with F5 and VMware.
